Generative Models

- Many applications such as image synthesis, denoising, super-resolution, speech synthesis, compression, etc. require to go beyond classification and regression, and model explicitly a high dimension signal.
- This modeling consists of finding "meaningful degrees of freedom" that describe the signal, and are of lesser dimension.

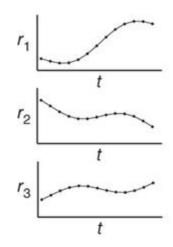

Definition

- Unsupervised learning refers to most attempts to extract information from a distribution that do not require human labor to annotate example
- Main task is to find the 'best' representation of the data

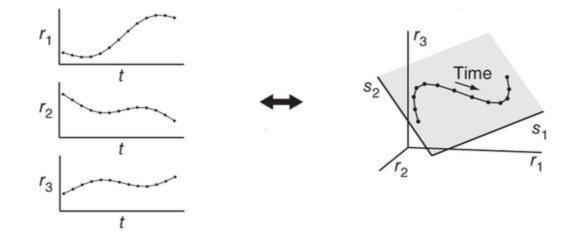

Dimension Reduction

- Attempt to compress as much information as possible in a smaller representation
- Preserve as much information as possible while obeying some constraint aimed at keeping the representation simpler

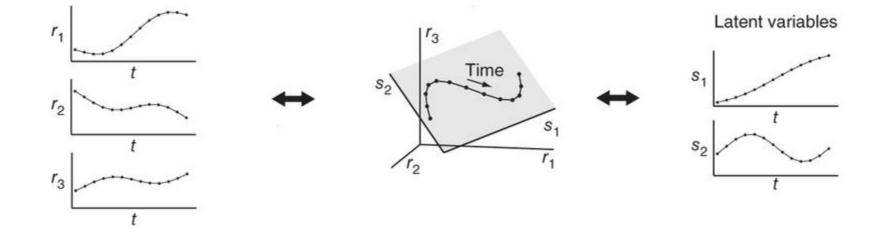

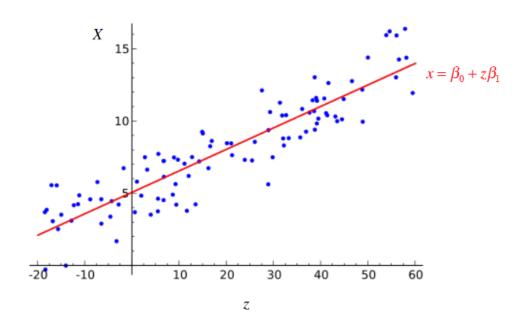

Recap: Linear Regression

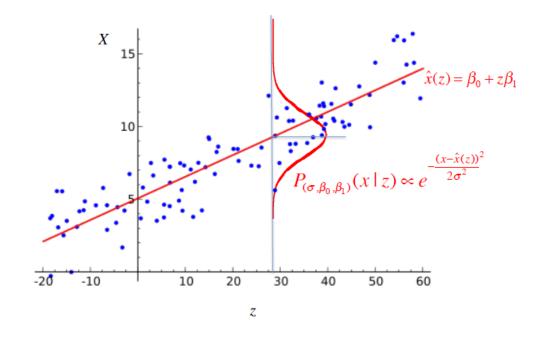

• Most people think of linear regression as points and a straight line:

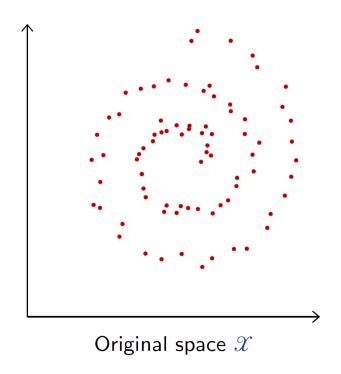

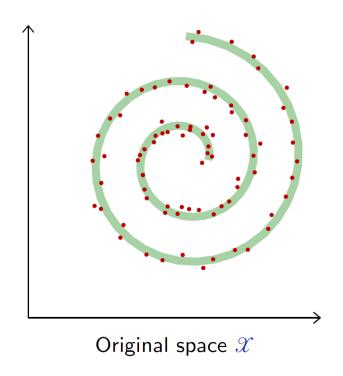

Recap: Linear Regression

- Statisticians additionally have $P_{\theta}(X|Z)$
- True model
 - May not be too complicated as opposed to original data
- Observed data = true model + error
- Benefits of having an error model:
 - How likely is a data point
 - Confidence bounds
 - Compare models
- Q: how to find an unseen true model (we never know the true model)

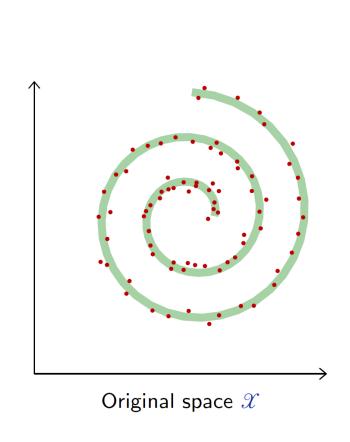

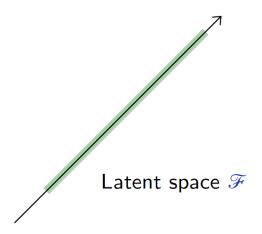

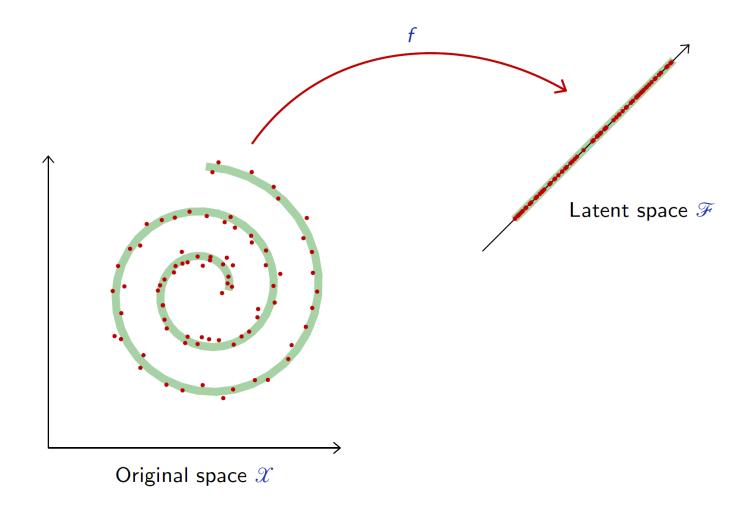

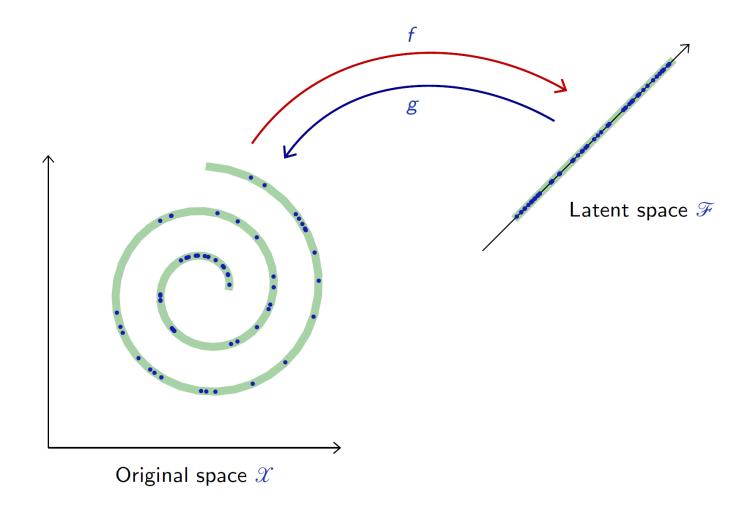

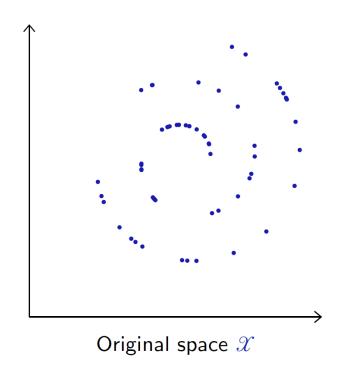

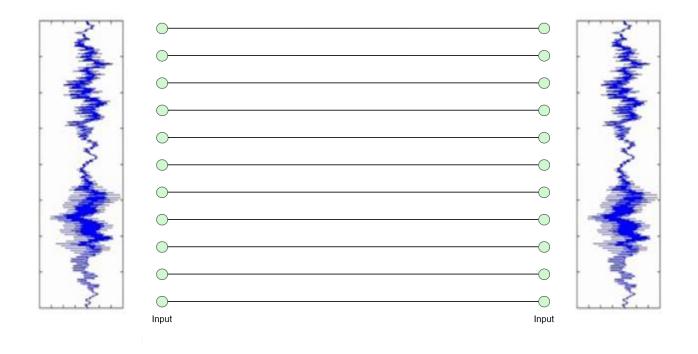

• We can generate data

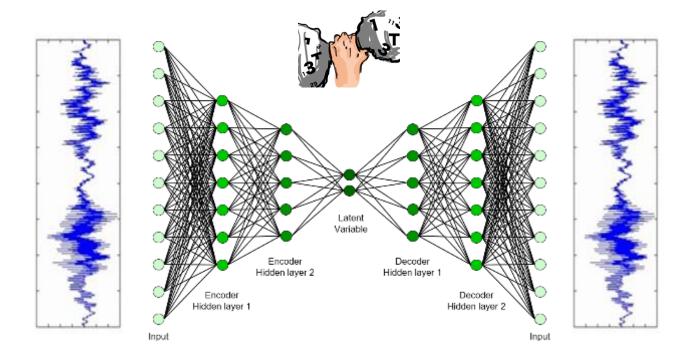

- It is like 'deep learning version' of unsupervised learning
- Definition
 - An autoencoder is a neural network that is trained to attempt to copy its input to its output
 - The network consists of two parts: an encoder and a decoder that produce a reconstruction
- Encoder and Decoder
 - Encoder function : z = f(x)
 - Decoder function : x = g(z)
 - We learn to set g(f(x)) = x

- Dimension reduction
- Recover the input data

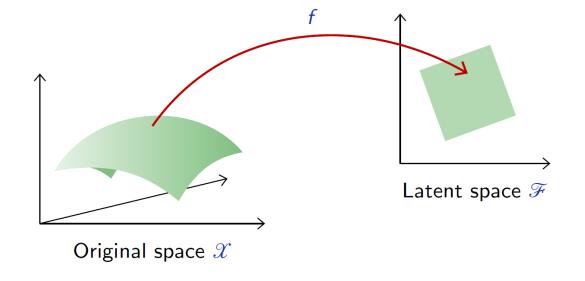

- Dimension reduction
- Recover the input data
 - Learns an encoding of the inputs so as to recover the original input from the encodings as well as possible

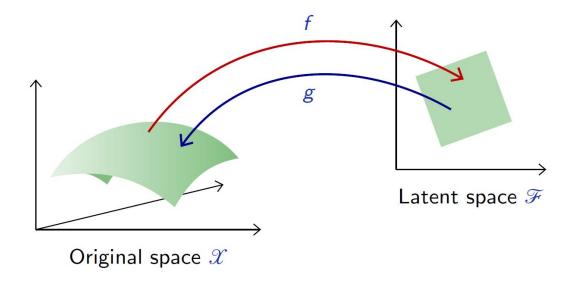

• Autoencoder combines an encoder f from the original space \mathcal{X} to a latent space \mathcal{F} , and a decoder g to map back to \mathcal{X} , such that $g \circ f$ is [close to] the identity on the data

• Autoencoder combines an encoder f from the original space \mathcal{X} to a latent space \mathcal{F} , and a decoder g to map back to \mathcal{X} , such that $g \circ f$ is [close to] the identity on the data

• A proper autoencoder has to capture a "good" parametrization of the signal, and in particular the statistical dependencies between the signal components.

Let q be the data distribution over \mathcal{X} . A good autoencoder could be characterized with the quadratic loss

$$\mathbb{E}_{X\sim q}\Big[\|X-g\circ f(X)\|^2\Big]\simeq 0.$$

Given two parametrized mappings $f(\cdot; w)$ and $g(\cdot; w)$, training consists of minimizing an empirical estimate of that loss

$$\hat{w}_f, \hat{w}_g = \underset{w_f, w_g}{\operatorname{argmin}} \frac{1}{N} \sum_{n=1}^N \|x_n - g(f(x_n; w_f); w_g)\|^2.$$

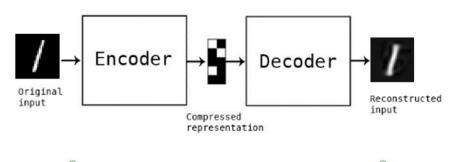

A simple example of such an autoencoder would be with both f and g linear, in which case the optimal solution is given by PCA. Better results can be achieved with more sophisticated classes of mappings, in particular deep architectures.

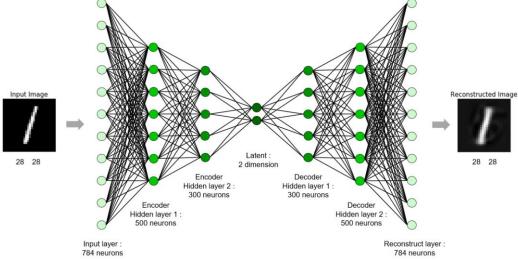

Autoencoder with MNIST

Autoencoder with TensorFlow

- MNIST example
- Use only (1, 5, 6) digits to visualize in 2-D

Import Libraries and Load MNIST Data

```
import numpy as np
import matplotlib.pyplot as plt
import tensorflow as tf
%matplotlib inline

from tensorflow.examples.tutorials.mnist import input_data
mnist = input_data.read_data_sets("MNIST_data/", one_hot=True)
```

• Only use (1, 5, 6) digits to visualize latent space in 2-D

```
train_idx = ((np.argmax(mnist.train.labels, 1) == 1) | \
            (np.argmax(mnist.train.labels, 1) == 5)  \
            (np.argmax(mnist.train.labels, 1) == 6))
test idx = ((np.argmax(mnist.test.labels, 1) == 1) \
           (np.argmax(mnist.test.labels, 1) == 5) \
           (np.argmax(mnist.test.labels, 1) == 6))
           = mnist.train.images[train idx]
train imgs
train labels = mnist.train.labels[train idx]
                                                           The number of training images: 16583, shape: (16583, 784)
            = mnist.test.images[test idx]
test imgs
                                                           The number of testing images: 2985, shape: (2985, 784)
test labels = mnist.test.labels[test idx]
n train
            = train_imgs.shape[0]
            = test imgs.shape[0]
n_test
print ("The number of training images : {}, shape : {}".format(n train, train imgs.shape))
print ("The number of testing images : {}, shape : {}".format(n test, test imgs.shape))
```

Structure of Autoencoder

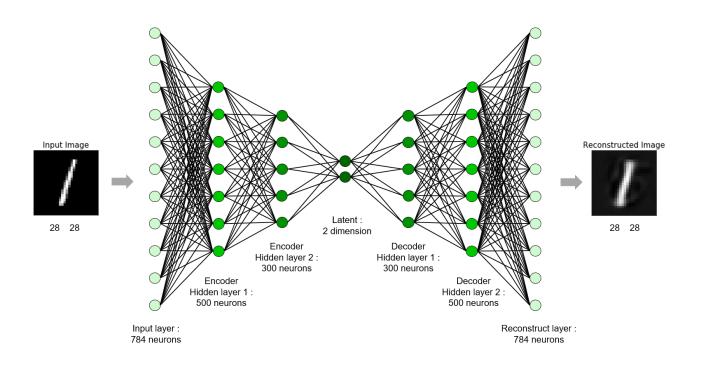

- Input shape and latent variable shape
- Encoder shape
- Decoder shape

```
# Shape of input and latent variable
n_input = 28*28

# Encoder structure
n_encoder1 = 500
n_encoder2 = 300

n_latent = 2

# Decoder structure
n_decoder1 = 300
n_decoder2 = 500
```

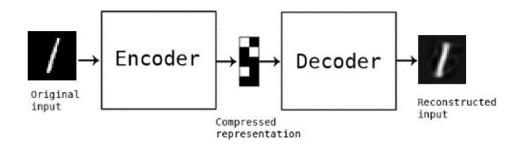

Weights & Biases, and Placeholder

- Define weights and biases for encoder and decoder, separately
- Based on the pre-defined layer size
- Initialize with normal distribution of $\mu=0$ and $\sigma=0.1$

```
weights = {
    'encoder1' : tf.Variable(tf.random_normal([n_input, n_encoder1], stddev=0.1)),
    'encoder2' : tf.Variable(tf.random_normal([n_encoder1, n_encoder2], stddev=0.1)),
    'latent' : tf.Variable(tf.random_normal([n_encoder2, n_latent], stddev=0.1)),
    'decoder1' : tf.Variable(tf.random_normal([n_latent, n_decoder1], stddev=0.1)),
    'decoder2' : tf.Variable(tf.random_normal([n_decoder1, n_decoder2], stddev=0.1)),
    'reconst' : tf.Variable(tf.random_normal([n_decoder2, n_input], stddev=0.1)))
}
biases = {
    'encoder1' : tf.Variable(tf.random_normal([n_encoder1], stddev=0.1)),
    'latent' : tf.Variable(tf.random_normal([n_latent], stddev=0.1)),
    'decoder1' : tf.Variable(tf.random_normal([n_latent], stddev=0.1)),
    'decoder1' : tf.Variable(tf.random_normal([n_decoder1], stddev=0.1)),
    'decoder2' : tf.Variable(tf.random_normal([n_decoder2], stddev=0.1)),
    'reconst' : tf.Variable(tf.random_normal([n_input], stddev=0.1)))
```

```
x = tf.placeholder(tf.float32, [None, n_input])
```

Build a Model

```
def encoder(x, weights, biases):
    encoder1 = tf.add(tf.matmul(x, weights['encoder1']), biases['encoder1'])
    encoder1 = tf.nn.tanh(encoder1)

encoder2 = tf.add(tf.matmul(encoder1, weights['encoder2']), biases['encoder2'])
    encoder2 = tf.nn.tanh(encoder2)

latent = tf.add(tf.matmul(encoder2, weights['latent']), biases['latent'])

return latent
```

```
def decoder(latent, weights, biases):
    decoder1 = tf.add(tf.matmul(latent, weights['decoder1']), biases['decoder1'])
    decoder1 = tf.nn.tanh(decoder1)

decoder2 = tf.add(tf.matmul(decoder1, weights['decoder2']), biases['decoder2'])
    decoder2 = tf.nn.tanh(decoder2)

reconst = tf.add(tf.matmul(decoder2, weights['reconst']), biases['reconst'])

return reconst
```

Loss and Optimizer

- Loss
 - Squared loss

$$\frac{1}{m}\sum_{i=1}^m (t_i-y_i)^2$$

- Optimizer
 - AdamOptimizer: the most popular optimizer

```
LR = 0.0001

latent = encoder(x, weights, biases)
reconst = decoder(latent, weights, biases)
loss = tf.square(tf.subtract(x, reconst))
loss = tf.reduce_mean(loss)

optm = tf.train.AdamOptimizer(LR).minimize(loss)
```

Define Optimization Configuration and Batch Maker

- Define parameters for training autoencoder
 - n_batch: batch size for mini-batch gradient descent
 - n_iter: the number of iterations steps
 - n_prt: check loss for every n_prt iteration

```
n_batch = 50
n_iter = 2500
n_prt = 250
```

Batch maker

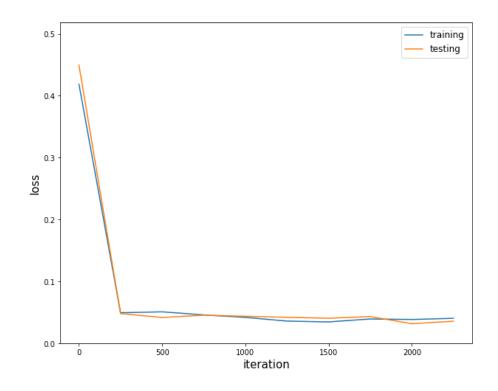

```
def train_batch_maker(batch_size):
    random_idx = np.random.randint(n_train, size = batch_size)
    return train_imgs[random_idx], train_labels[random_idx]

def test_batch_maker(batch_size):
    random_idx = np.random.randint(n_test, size = batch_size)
    return test_imgs[random_idx], test_labels[random_idx]
```

Optimization

```
sess = tf.Session()
init = tf.global variables initializer()
sess.run(init)
loss_record_train = []
loss record test = []
for epoch in range(n_iter):
   train_x, _ = train_batch_maker(n_batch)
   sess.run(optm, feed dict = {x : train x})
   if epoch % n prt == 0:
       test_x, _ = test_batch_maker(n_batch)
        c1 = sess.run(loss, feed_dict = {x: train_x})
        c2 = sess.run(loss, feed_dict = {x: test_x})
        loss record train.append(c1)
        loss record test.append(c2)
        print ("Iter : {}".format(epoch))
        print ("Cost : {}".format(c1))
```

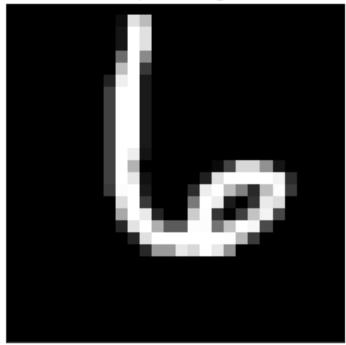

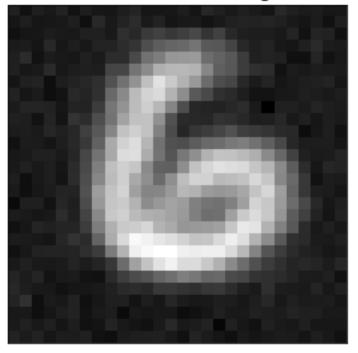

Test or Evaluation

```
test_x, _ = test_batch_maker(1)
x_reconst = sess.run(reconst, feed_dict = {x: test_x})
```

Reconstructed Image

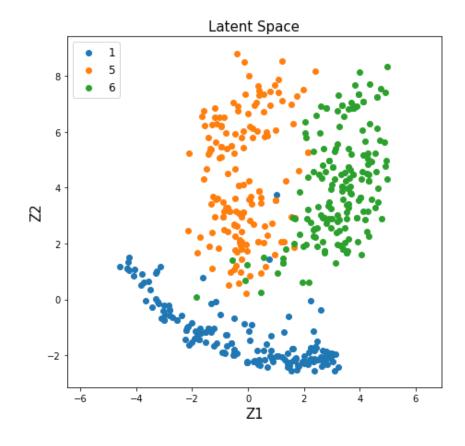

Distribution in Latent Space

• Make a projection of 784-dim image onto 2-dim latent space

```
test_x, test_y = test_batch_maker(500)
test_y = np.argmax(test_y, axis = 1)
test_latent = sess.run(latent, feed_dict = {x: test_x})
```

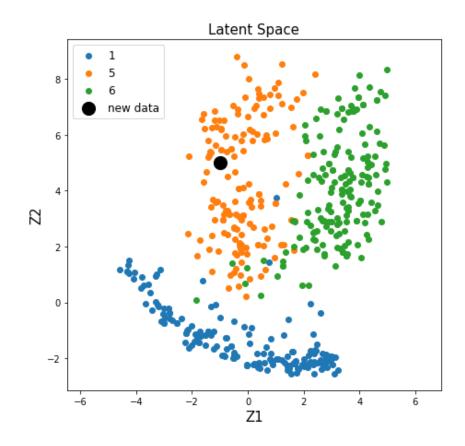

Data Generation

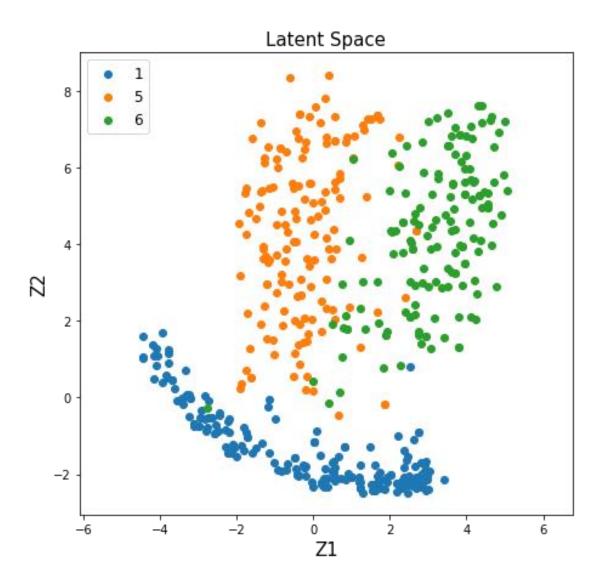

```
new_data = np.array([[-1, 5]])

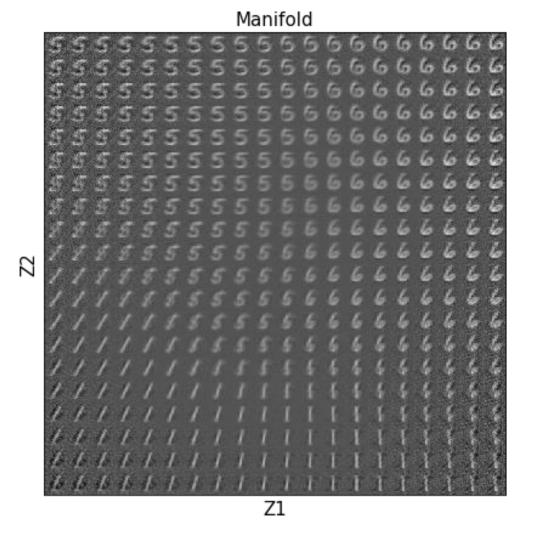

latent_input = tf.placeholder(tf.float32, [None, n_latent])
reconst = decoder(latent_input, weights, biases)
fake_image = sess.run(reconst, feed_dict = {latent_input: new_data})
```

Visualization

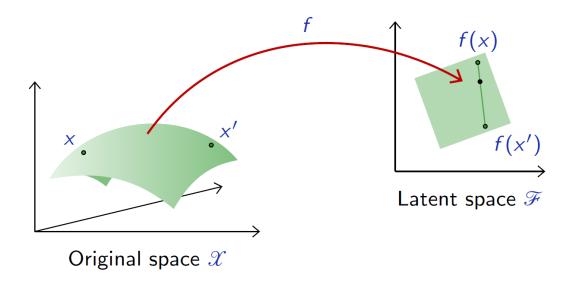

Autoencoder as Generative Model

Latent Representation

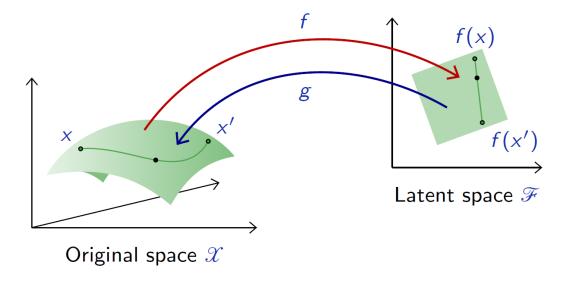

• To get an intuition of the latent representation, we can pick two samples x and x' at random and interpolate samples along the line in the latent space

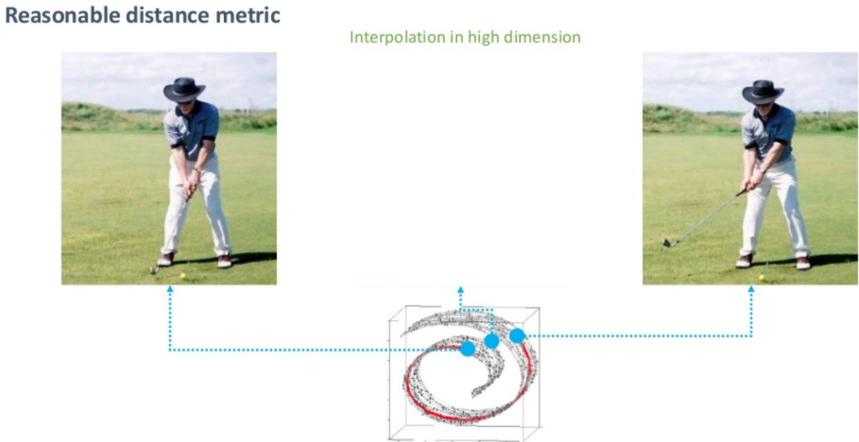

Latent Representation

• To get an intuition of the latent representation, we can pick two samples x and x' at random and interpolate samples along the line in the latent space

$$\forall x, x' \in \mathcal{X}^2, \ \alpha \in [0, 1], \ \xi(x, x', \alpha) = g((1 - \alpha)f(x) + \alpha f(x')).$$

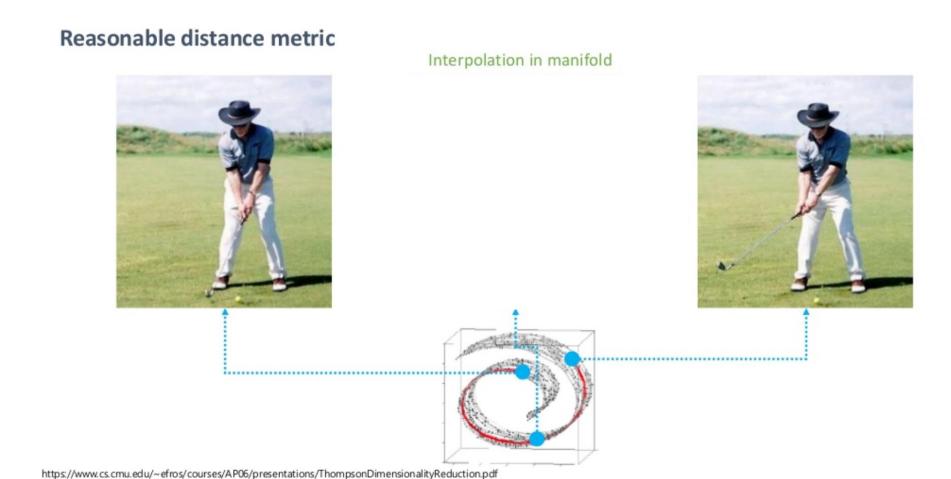

Interpolation in High Dimension

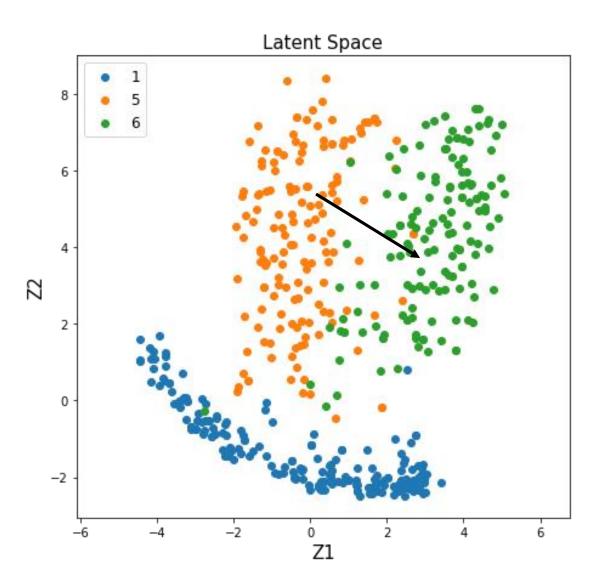

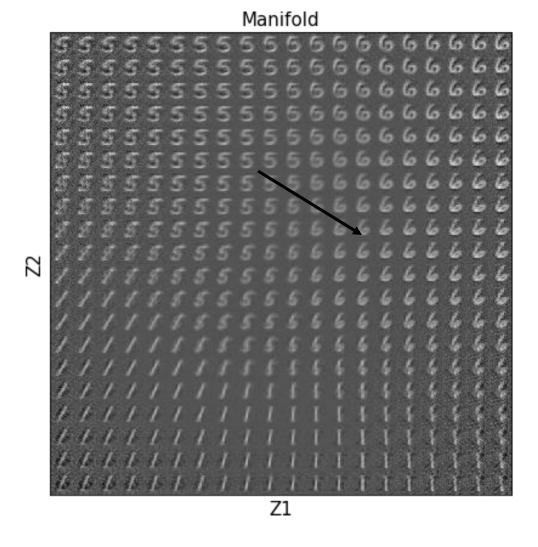

Interpolation in Manifold

MNIST Example

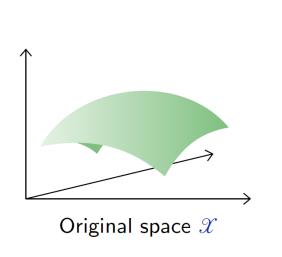

Generative Capabilities

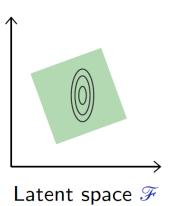

• We can assess the generative capabilities of the decoder g by introducing a [simple] density model q^Z over the latent space \mathcal{F} , sample there, and map the samples into the image space \mathcal{X} with g.

We can for instance use a Gaussian model with diagonal covariance matrix.

$$f(X) \sim \mathcal{N}(\hat{m}, \hat{\Delta})$$

where \hat{m} is a vector and $\hat{\Delta}$ a diagonal matrix, both estimated on training data.

where \hat{m} is a vector and $\hat{\Delta}$ a diagonal matrix, both estimated on training data.

MNIST Example

Generative Models

- It generates something that makes sense.
- These results are unsatisfying, because the density model used on the latent space ${\mathcal F}$ is too simple and inadequate.
- Building a "good" model amounts to our original problem of modeling an empirical distribution, although it may now be in a lower dimension space.
- This is a motivation to VAE or GAN.
