IX 4.9 Optimization

1. Artificial Neural Networks (ANN)

1.1 Structure

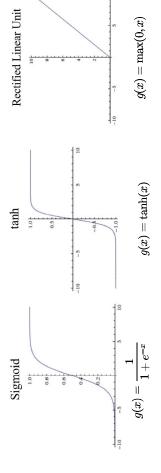

Transformation

• Affine (or linear) transformation and nonlinear activation (layer)

$$f(x) = g\left(heta^T x + b
ight)$$

Nonlinear activation function

1.2. Training Neural Networks

Loss Function

- Measures error between target values and predictions
- More or less the same as those for other parametric models, such as linear models

$$\min_{\theta} \sum_{i=1}^{m} \ell\left(h_{\theta}\left(x^{(i)}\right), y^{(i)}\right)$$

- Example
- Cross entropy:

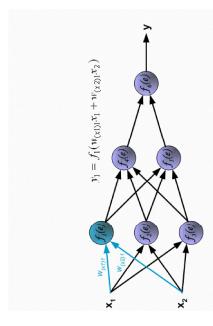

$$-\frac{1}{N}\sum_{i=1}^{N}y^{(i)}\log\Bigl(h_{\theta}\left(x^{(i)}\right)\Bigr)+\Bigl(1-y^{(i)}\Bigr)\log\Bigl(1-h_{\theta}\left(x^{(i)}\right)\Bigr)$$

Squared loss:

$$rac{1}{N}\sum_{i=1}^{N}\left(h_{ heta}\left(x^{(i)}
ight)-y^{(i)}
ight)^{2}$$

Backpropagation

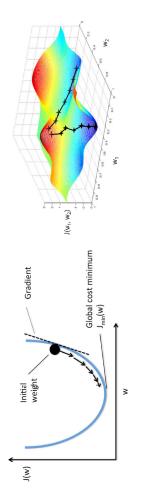

- Forward propagation
- the initial information propagates up to the hidden units at each layer and finally produces output
- Backpropagation
 allows the information from the cost to flow backwards through the network in order to compute the gradients

(Stochastic) Gradient Descent

- Negative gradients points directly downhill of cost function
- We can decrease cost by moving in the direction of the negative gradient ($\!\alpha$ is a learning rate)

$$heta:= heta-lpha
abla_{ heta}\left(h_{ heta}\left(x^{(i)}
ight),y^{(i)}
ight)$$

2. Deep Learning Libraries

- Platform: Linux, Mac OS, Windows
 - Written in: C++
- Interface: Python, MATLAB

Theano

theano

- Platform: Cross-platform
 Written in: Python
- Interface: Python

Tensorflow

- Platform: Linux, Mac OS, Windows
 - Written in: C++, Python
- Interface: Python, C/C++, Java, Go, R

3. TensorFlow

tensorflow is an open-source software library for deep learning.

3.1. Computational Graph

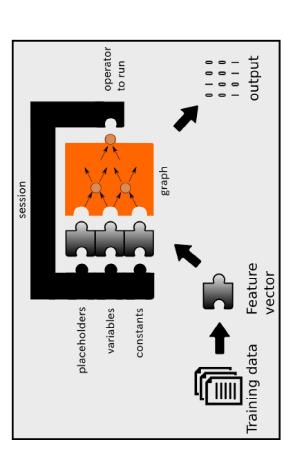

- tf.constant
 - tf.Variable
- tf.placeholder

```
a = tf.constant([1, 2, 3])
b = tf.constant([4, 5, 6])
In [1]: import tensorflow as tf
                                                                                                    A = a + b
B = a * b
```

Out[2]: <tf.Tensor 'add:0' shape=(3,) dtype=int32>

Out[3]: <tf.Tensor 'mul:0' shape=(3,) dtype=int32>

To run any of the three defined operations, we need to create a session for that graph. The session will also allocate memory to store the current value of the variable.

In [4]: sess = tf.Session()

sess.run(A)

Out[4]: array([5, 7, 9])

In [5]: sess.run(B)

Out[5]: array([4, 10, 18])

tf. Variable is regarded as the decision variable in optimization. We should initialize variables to use tf. Variable.

Out[8]: array([1, 1]) In [8]: sess.run(w)

The value of tf.placeholder must be fed using the feed_dict optional argument to Session.run().

3.2. Example: Linear Regression using TensorFlow

Given $\left\{ egin{array}{l} x_i : ext{inputs} &, ext{Find} \, \omega_1 \, ext{and} \, \omega_2 \ y_i : ext{outputs} &, ext{} \end{array}
ight.$

$$x=egin{bmatrix} x_1 \ x \ \end{array} egin{bmatrix} x_1 \ x \ \end{array} egin{bmatrix} x_2 \ \vdots \ \end{array} , \qquad y=egin{bmatrix} y_2 \ \vdots \ \vdots \ \end{array} pprox \hat{y}_i=\omega_1 x_i+\omega_2$$

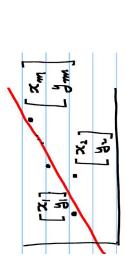

• \hat{y}_i : predicted output

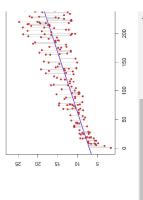

•
$$\omega = egin{bmatrix} \omega_1 \ \omega_2 \end{bmatrix}$$
 : Model parameters

$$\hat{y}_i = f(x_i, \omega)$$
 in general

• in many cases, a linear model to predict y_i used

$$\hat{y}_i = \omega_1 x_i + \omega_2 \; ext{ such that } \min_{\omega_1, \omega_2} \sum_{i=1}^m (\hat{y}_i - y_i)^2$$

Data Generation

```
print(np.random.rand(10))
print(np.random.randint(0,10,size=10))
In [11]: import numpy as np
```

optm = tf.train.GradientDescentOptimizer(LR).minimize(loss)

init = tf.global_variables_initializer()
sess = tf.Session()

sess.run(init)

In [18]: | # tf.Variable initializer

optm = tf.train.AdamOptimizer(LR).minimize(Loss)

In [17]: \mid # define optimizer

LR = 0.04

Prameter Learning (or Estimation) by using TensorFlow

```
In [13]: # Define decision variables in tf weights = {
    weights = {
        'w' : tf.Variable(tf.random_normal([1], stddev=0.1))
    } biases = {
        'b' : tf.Variable(tf.random_normal([1], stddev=0.1))
}

In [14]: x = tf.placeholder(tf.float32, [10])
y = tf.placeholder(tf.float32, [10])
In [15]: # define model

def model(x, weights, biases):
    output = tf.add(tf.multiply(x, weights['w']), biases['b'])
    return output
```

pred = model(x, weights, biases)
loss = tf.square(tf.subtract(y, pred))

In [16]: # define loss

 $\min_{\omega,b} rac{1}{m} \sum_{i=1}^m (y_i - \hat{y}_i)^2$

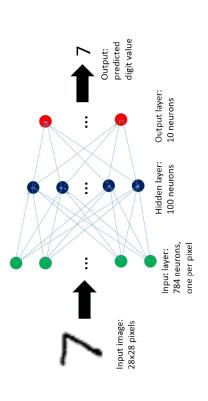

loss = tf.reduce_mean(loss)

```
c = sess.run(loss, feed_dict={x: train_x, y: train_y})
print ("Iter : {}".format(epoch))
print ("Cost : {}".format(c))
                                                                                                                                               sess.run(optm, feed_dict={x: train_x, y: train_y})
                                                                                                            idx = np.random.randint(0, 100, 10)
train_x, train_y = data_x[idx], data_y[idx]
                                                                                                                                                                                                                                                                                                w_hat = sess.run(weights['w'])
b_hat = sess.run(biases['b'])
                                                                                          for epoch in range(n_iter):
                                                                                                                                                                                  if epoch % n_prt == 0:
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    Cost : 0.08917944133281708

4. ANN with TensorFlow

- MNIST (Mixed National Institute of Standards and Technology database) database
 - Handwritten digit database
 - ullet 28 imes 28 gray scaled image
- $_{\rm \blacksquare}$ Flattened array into a vector of $28\times28=784$

In [21]: | **%html**

4.1. Import Library

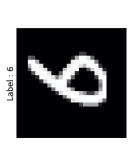

In [22]: # Import Library
 import numpy as np
 import matplotlib.pyplot as plt
 import tensorflow as tf

4.2. Load MNIST Data

Download MNIST data from tensorflow tutorial example

```
In [23]: from tensorflow.examples.tutorials.mnist import input_data
mnist = input_data.read_data_sets("MNIST_data/", one_hot=True)

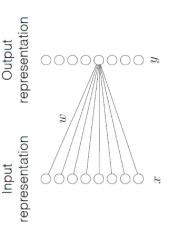

Extracting MNIST_data/train-images-idx3-ubyte.gz
Extracting MNIST_data/train-labels-idx1-ubyte.gz
Extracting MNIST_data/ti0k-images-idx3-ubyte.gz
Extracting MNIST_data/t10k-images-idx3-ubyte.gz
Extracting MNIST_data/t10k-labels-idx1-ubyte.gz
```

One hot encoding

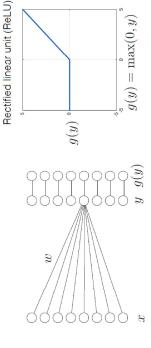

4.3. Build a Model

First, the layer performs several matrix multiplication to produce a set of linear activations

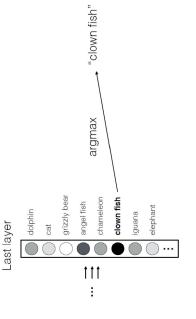

Second, each linear activation is running through a nonlinear activation function

hidden1 = tf.nn.relu(hidden1)

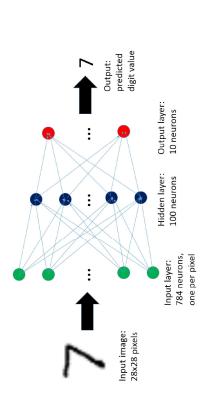

Third, predict values with affine transformation

output = tf.matmuL(hidden1, weights['output']) + biases['output']
output = tf.add(tf.matmul(hidden1, weights['output']), biases['output'])

4.4. Define an ANN Shape

- Input size
- Hidden layer size
- The number of classes

4.5. Define Weights, Biases and Network

- Define parameters based on predefined layer size
- Initialize with normal distribution with $\mu=0$ and $\sigma=0.1$

4.6. Define Cost, Initializer and Optimizer

Loss

- Classification: Cross entropy
- Equivalent to apply logistic regression

$$-\frac{1}{N}\sum_{i=1}^{N}y^{(i)}\log(h_{\theta}\left(x^{(i)}\right))+(1-y^{(i)})\log(1-h_{\theta}\left(x^{(i)}\right))$$

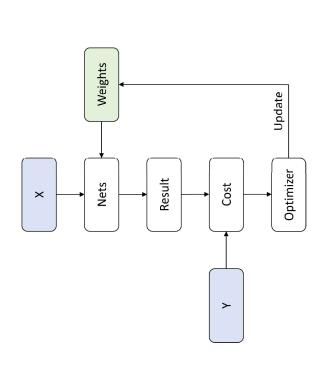

Initializer

Initialize all the empty variables

Optimizer

AdamOptimizer: the most popular optimizer

4.7. Summary of Model

4.8. Define Configuration

- Define parameters for training ANN
- n_batch : batch size for stochastic gradient descent
- n_iter: the number of learning steps
- n_prt : check loss for every n_prt iteration

```
In [30]: n_batch = 50 # Batch Size
n_iter = 2500 # Learning Iteration
n_prt = 250 # Print Cycle
```

4.9. Optimization

```
# config = tf.ConfigProto(allow_soft_placement=True) # GPU Allocating policy
# sess = tf.Session(config=config)
sess = tf.Session()
