### **Linear Regression Examples**

- De-noising
- Total Variation

### **De-noising Signal**

- We start with a signal represented by a vector  $x \in \mathbb{R}^n$ 
  - $-x_i$  corresponds to the value of some function of time, evaluated (or sampled) at evenly spaced points.
- Suppose x is corrupted by some small, rapidly varying noise  $\varepsilon$ ,
  - i.e.  $x_{cor} = x + \varepsilon$

## **Transform it to an Optimization Problem**

- Transform de-noising in time into an optimization problem
- It is usually assumed that the signal does not vary too rapidly, which means that usually, we have  $x_i \approx x_{i+1}$

$$X = egin{bmatrix} x_1 \ x_2 \ dots \ x_n \end{bmatrix} \qquad \min_{X} \; \left\{ egin{array}{c} \|(X - X_{cor})\|_2^2 \ ext{how much } x ext{ deviates from } x_{cor} \end{array} + \mu \; \sum_{k=1}^{n-1} (x_{k+1} - x_k)^2 \ ext{penalize rapid changes of } X \end{array} 
ight\}$$

- $\bullet$   $\mu$ 
  - to adjust the relative weight of the first and second terms
  - to controls the "smoothness" of  $\hat{x}$

### **Signal with Sharp Transition + Noise**

• Suppose we have a signal x, which is mostly smooth, but has several rapid variations

(or jumps).

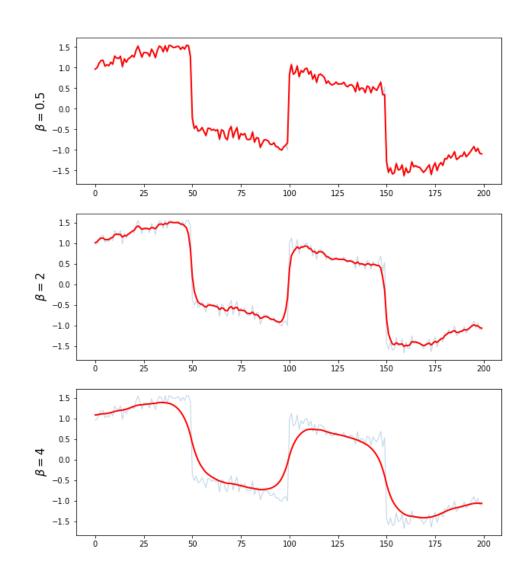

- First, apply the same method that we used for smoothing signals before
- known as a total variation problem

### Quadratic Smoothing ( $L_2$ Norm)

$$egin{array}{ll} \min \|Dx\|_2 \ s.\,t. & \|x-x_{cor}\|_2 < eta \end{array}$$

- Quadratic smoothing smooths out both noise and sharp transitions in signal, but this is not what we want
- We will not be able to preserve the signal's sharp transitions.

Any ideas ?

### $L_1$ Norm

· We can instead apply total variation reconstruction on the signal by solving

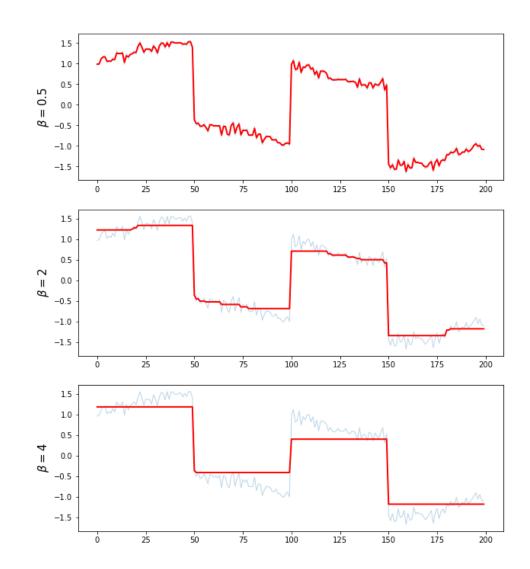

$$\min \|x - x_{cor}\|_2 + \lambda \sum_{i=1}^{n-1} |x_{i+1} - x_i|_2$$

where the parameter  $\lambda$  controls the "smoothness" of x

### $L_1$ Norm

$$egin{array}{ll} \min \|Dx\|_1 \ s.\,t. & \|x-x_{cor}\|_2 < eta \end{array}$$

- Total Variation (TV) smoothing preserves sharp transitions in signal, and this is not bad
- Note that how TV reconstruction does a better job of preserving the sharp transitions in the signal while removing the noise.

### **Total Variation Image Reconstruction**

• Q: Apply  $L_1$  norm to the image, and guess what kind of an image will be produced?

const = [cvx.norm(x - imbws, 2) <= beta]
prob = cvx.Problem(obj, const).solve()
