1. De-noising Signal

We start with a signal represented by a vector $x \in \mathbb{R}^n$. The coefficients x_i correspond to the value of some function of time, evaluated (or *sampled*, in the language of signal processing) at evenly spaced points. It is usually assumed that the signal does not vary too rapidly, which means that usually, we have $x_i \approx x_{i+1}$.

Suppose we have a signal x, which does not vary too rapidly and that x is corrupted by some small, rapidly varying noise v, i.e. $x_{cor} = x + v$.

Then if we want to reconstruct x from x_{cor} we should solve (with \hat{x} as the parameter)

$$ext{minimize} \quad \|\hat{x} - x_{cor}\|_2 + \lambda \sum_{i=1}^{n-1} (x_{i+1} - x_i)^2$$

where the parameter λ controls the "smoothnes" of \hat{x} .

```

1.1. Transform de-noising in time into an optimization problem

$$\min_{X} \left\{ \underbrace{ \underbrace{ \left\| (X - X_{cor})
ight\|_{2}^{2} }_{ ext{how much } x ext{ deviates from } x_{cor}} + \mu \underbrace{\sum_{k=1}^{n-1} (x_{k+1} - x_{k})^{2} }_{ ext{penalize rapid changes of } X}
ight\}$$

- 1) $\min_{X} \, \|(X-X_{cor})\|_2^2$: How much X deviates from X_{cor}
- 2) $\mu \sum\limits_{k=1}^{n-1} (x_{k+1}-x_k)^2$: penalize rapid changes of X
- 3) μ : to adjust the relative weight of 1) & 2)

$$X = egin{bmatrix} x_1 \ x_2 \ dots \ x_n \end{bmatrix}$$

1)
$$X - X_{cor} = I_n X - X_{cor}$$

2)
$$\sum (x_{k+1}-x_k)^2 \implies$$

$$(x_2-x_1)-0=[-1, \ 1, \ 0, \ \cdots \ 0] egin{bmatrix} x_1 \ x_2 \ \vdots \ x_n \ \end{bmatrix} - 0 \ \vdots \ x_1 \ x_2 \ \vdots \ x_n \ \end{bmatrix} - 0 \ \vdots \ \vdots \ x_n \ \end{bmatrix} = 0 \ \end{bmatrix}$$
 $\Rightarrow \begin{bmatrix} -1 & 1 & 0 & \cdots & 0 & 0 \ 0 & -1 & 1 & \cdots & 0 & 0 \ 0 & -1 & 1 & \cdots & 0 & 0 \ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \ 0 & 0 & \cdots & -1 & 1 \end{bmatrix} \begin{bmatrix} x_1 \ x_2 \ \vdots \ x_n \ \end{bmatrix} - \begin{bmatrix} 0 \ 0 \ \vdots \ 0 \ \end{bmatrix} \begin{bmatrix} 2 \ 0 \ \vdots \ 0 \end{bmatrix}$

$$egin{aligned} \left\|I_{n}X-X_{cor}
ight\|_{2}^{2} + \mu \left\|DX-0
ight\|_{2}^{2} &= \left\|Ax-b
ight\|_{2}^{2} \ &= \left\|igg[rac{I_{n}}{\sqrt{\mu}D}
ight]X-igg[rac{X_{cor}}{0}
ight]
ight\|_{2}^{2} \ \end{aligned}$$
 where $A=igg[rac{I_{n}}{\sqrt{\mu}D}igg],\quad b=igg[rac{X_{cor}}{0}igg]$

• Then, plug A, b into Python with cvxpy toolbox to numerically solve

In [3]:

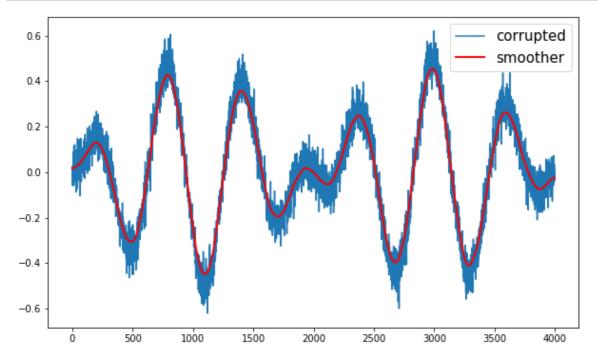

```
n = 4000
mu = 1000

D = np.zeros([n-1, n])
D[:,0:n-1] -= np.eye(n-1)
D[:,1:n] += np.eye(n-1)
A = np.vstack([np.eye(n), np.sqrt(mu)*D])
b = np.vstack([x_cor, np.zeros([n-1,1])])
A = np.asmatrix(A)
b = np.asmatrix(b)
```

In [4]:

```
x_reconst = (A.T*A).I*A.T*b

plt.figure(figsize=(10, 6))
plt.plot(t, x_cor, '-', label='corrupted');
plt.plot(t, x_reconst, 'r', label='smoother', linewidth=2)
plt.legend(fontsize=15)
plt.show()
```

1.2. with different μ 's (see how μ affects smoothing results)

```
plt.figure(figsize=(10, 9))
mu = [0, 1000, 1e4];

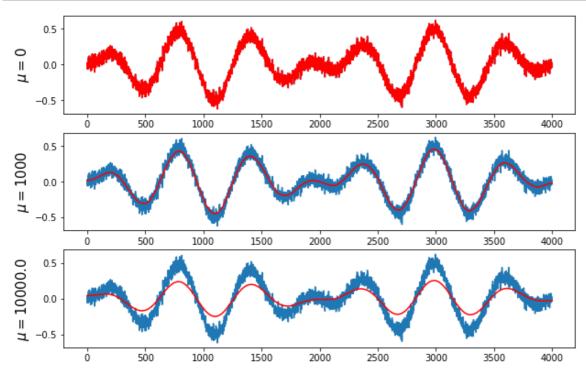

for i in range(len(mu)):
    A = np.vstack([np.eye(n), np.sqrt(mu[i])*D])
    b = np.vstack([x_cor, np.zeros([n-1,1])])

    A = np.asmatrix(A)
    b = np.asmatrix(b)

    x_reconst = (A.T*A).I*A.T*b

    plt.subplot(4,1,i+1)
    plt.plot(t, x_cor, '-')
    plt.plot(t, x_reconst, 'r')
    plt.ylabel('$\mu = {}$'.format(mu[i]), fontsize=15)

plt.show()
```

1.3. use CVXPY

 CVXPY strongly encourages to eliminate quadratic forms - that is, functions like sum_squares, sum(square(.)) or quad_form - whenever it is possible to construct equivalent models using norm instead

$$\min \ \left\{ \|x - x_{cor}\|_2^2 + \mu \|Dx\|_2^2
ight\}$$

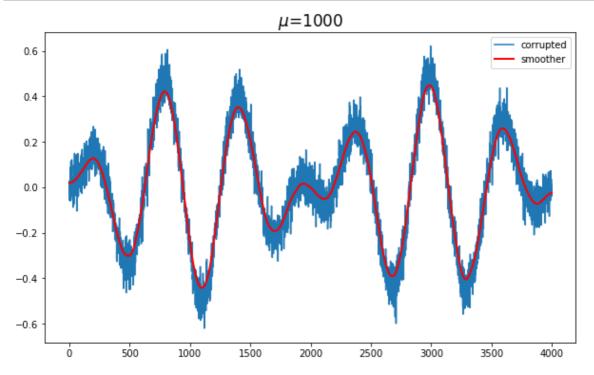

In [6]:

```
n = 4000
mu = 1000

x_reconst = cvx.Variable(n,1)
#obj = cvx.Minimize(cvx.sum_squares(x_reconst-x_cor) + mu*cvx.sum_squares(x_reconst[1:
n]-x_reconst[0:n-1]))
obj = cvx.Minimize(cvx.sum_squares(x_reconst-x_cor) + mu*cvx.sum_squares(D*x_reconst))
prob = cvx.Problem(obj).solve('SCS')
```

In [7]:

```
plt.figure(figsize=(10, 6))
plt.plot(t, x_cor)
plt.plot(t, x_reconst.value, 'r', linewidth = 2)
title = '=%s' % str(mu)
plt.title('$\mu$' + title, fontsize = 17)
plt.legend(['corrupted', 'smoother'], loc = 1)
plt.show()
```

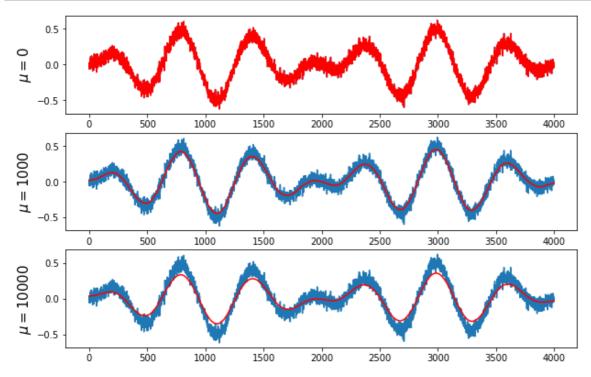

```
plt.figure(figsize=(10, 9))
mu = [0, 1000, 1e4]

for i in range(len(mu)):
    x_reconst = cvx.Variable(n,1)
    obj = cvx.Minimize(cvx.sum_squares(x_reconst-x_cor) + mu[i]*cvx.sum_squares(D*x_reconst))
    prob = cvx.Problem(obj).solve('SCS')

    plt.subplot(4,1,i+1)
    plt.plot(t,x_cor,'-')
    plt.plot(t,x_reconst.value,'r')
    plt.ylabel('$\mu = {}$'.format(int(mu[i])), fontsize=15)

plt.show()
```

1.4. L_2 norm

 CVXPY strongly encourages to eliminate quadratic forms - that is, functions like sum_squares, sum(square(.)) or quad_form - whenever it is possible to construct equivalent models using norm instead

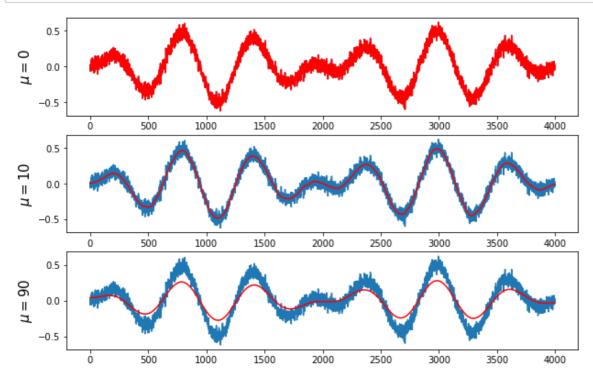

$$\min \ \left\{ \|x - x_{cor}\|_2 + \alpha \|Dx\|_2 \right\}$$

```
plt.figure(figsize=(10, 9))
alpha = [0, 10, 90]

for i in range(len(alpha)):
    x_reconst = cvx.Variable(n)
    obj = cvx.Minimize(cvx.norm(x_reconst-x_cor, 2) + alpha[i]*(cvx.norm(D*x_reconst, 2)))
    prob = cvx.Problem(obj).solve('SCS')

    plt.subplot(4,1,i+1)
    plt.plot(t,x_cor,'-')
    plt.plot(t,x_reconst.value,'r')
    plt.ylabel('$\mu = {}$'.format(int(alpha[i])), fontsize=15)

plt.show()
```

1.5. L_2 norm with a constraint

$$egin{aligned} \min & \|Dx\|_2 \ s.\,t. & \|x-x_{cor}\|_2 < eta \end{aligned}$$

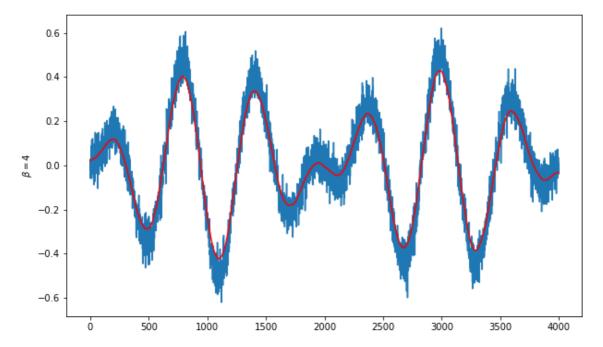

In [10]:

```
plt.figure(figsize=(10, 6))

beta = 4

x_reconst = cvx.Variable(n)
obj = cvx.Minimize(cvx.norm(D*x_reconst, 2))
const = [cvx.norm(x_reconst-x_cor, 2) <= beta]
prob = cvx.Problem(obj, const).solve(solver='SCS')

plt.plot(t,x_cor,'-')
plt.plot(t,x_reconst.value,'r')
plt.ylabel(r'$\beta = {}$'.format(beta))
plt.show()</pre>
```

In [11]:

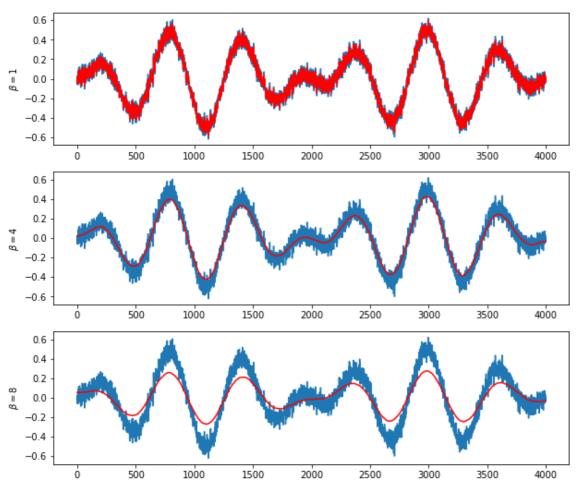

```
plt.figure(figsize=(10, 9))
beta = [1, 4, 8]

for i in range(len(beta)):

    x = cvx.Variable(n)
    obj = cvx.Minimize(cvx.norm(x[1:n] - x[0:n-1], 2))
    const = [cvx.norm(x-x_cor, 2) <= beta[i]]
    prob = cvx.Problem(obj, const).solve(solver='SCS')

    plt.subplot(len(beta),1,i+1)
    plt.plot(t,x_cor,'-')
    plt.plot(t,x.value,'r')
    plt.ylabel(r'$\beta = {}$'.format(int(beta[i])))

plt.show()</pre>
```

2. Signal with Sharp Transition + Noise

Suppose we have a signal x, which is mostly smooth, but has several rapid variations (or jumps). If we apply quadratic smoothing on this signal (see SMOOTHREC_CVX) then in order to remove the noise we will not be able to preserve the signal's sharp transitions.

- First, apply the same method that we used for smoothing signals before
- · known as a total variation problem
- · Source:
 - Chapter 6.3 from Boyd & Vandenberghe's book "<u>Convex Optimization</u> (http://stanford.edu/~boyd/cvxbook/)"
 - m files of total variation reconstruction
 (http://cvxr.com/cvx/examples/cvxbook/Ch06_approx_fitting/html/tv_cvx.html)

In [12]:

```
n = 2000
t = np.arange(n).reshape(-1,1)

exact = np.vstack([np.ones([500,1]), -np.ones([500,1]), np.ones([500,1]), -
np.ones([500,1])])

x = exact + 0.5*np.sin((2*np.pi/n)*t)
exact_variation = np.sum(np.abs(exact[1:n] - exact[0:n-1]))

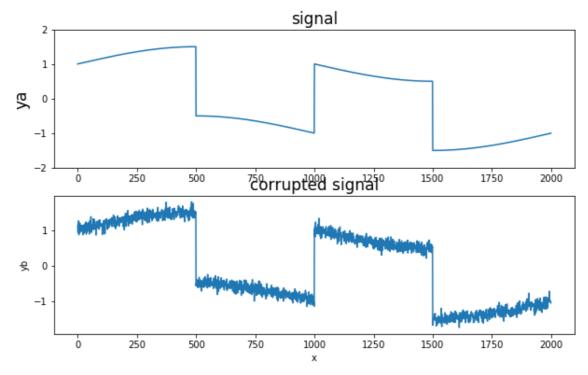

noise = 0.1*np.random.randn(n,1)
corrupt = x + noise
noise_variation = np.sum(np.abs(corrupt[1:n] - corrupt[0:n-1]))
```

In [13]:

```
plt.figure(figsize=(10, 6))

plt.subplot(2,1,1)
plt.plot(t,x)
plt.ylim([-2.0,2.0])
plt.title('signal' , fontsize = 17)
plt.ylabel('ya', fontsize = 17)

plt.subplot(2,1,2)
plt.plot(t, corrupt)
plt.title('corrupted signal' , fontsize = 17)
plt.ylabel('yb')
plt.xlabel('yb')
plt.show()
```

Quadratic Smoothing (L_2 norm)

In [14]:

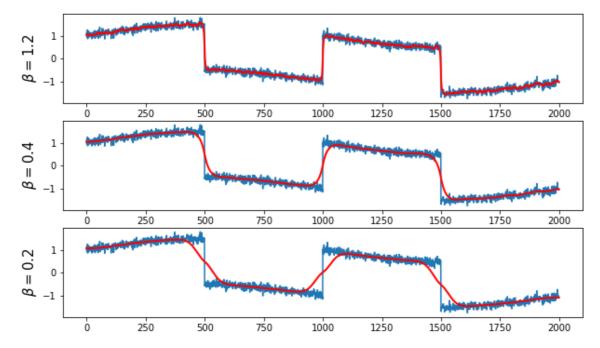

```
plt.figure(figsize=(10, 6))

beta = [1.2, 0.4, 0.2]

for i in range(len(beta)):
    x = cvx.Variable(n)
    obj = cvx.Minimize(cvx.norm(x-corrupt, 2))
    const = [cvx.norm(x[1:n] - x[0:n-1], 2) <= beta[i]]
    prob = cvx.Problem(obj, const).solve('SCS')

plt.subplot(len(beta), 1, i+1)
    plt.plot(t, corrupt)
    plt.plot(t, x.value, 'r', linewidth=2)
    plt.ylabel(r'$\beta = {}$'.format(beta[i]), fontsize=15)

plt.show()</pre>
```

- Quadratic smoothing smooths out noise and sharp transitions in signal, but this is not what we want
- · Any ideas?

L_1 Norm

We can instead apply total variation reconstruction on the signal by solving

$$\min \|x - x_{cor}\|_2 + \lambda \sum_{i=1}^{n-1} |x_{i+1} - x_i|$$

where the parameter lambda controls the "smoothness" of x.

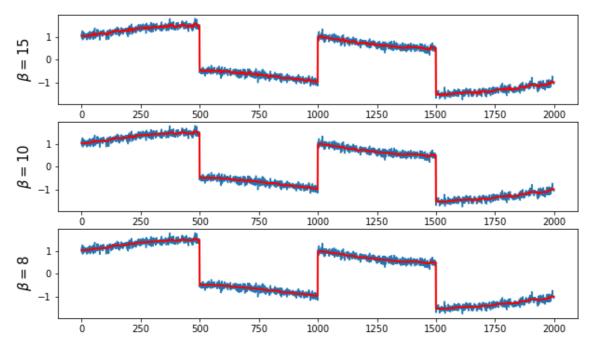

```
plt.figure(figsize=(10, 6))

beta = [15, 10, 8]

for i in range(len(beta)):
    x = cvx.Variable(n)
    obj = cvx.Minimize(cvx.norm(x-corrupt, 2))
    const = [cvx.norm(x[1:n] - x[0:n-1], 1) <= beta[i]]
    prob = cvx.Problem(obj, const).solve('SCS')

plt.subplot(len(beta), 1, i+1)
    plt.plot(t, corrupt)
    plt.plot(t, x.value, 'r', linewidth=2)
    plt.ylabel(r'$\beta = {}$'.format(beta[i]), fontsize=15)

plt.show()</pre>
```

- Total variation smoothing preserves sharp transitions in signal, and this is not bad
- Note how TV reconstruction does a better job of preserving the sharp transitions in the signal while removing the noise.

3. Total Variation Image Reconstruction

idea comes from http://www2.compute.dtu.dk/~pcha/mxTV/)

In [16]:

```
import scipy as sc

imbw = sc.misc.imread('./image_files/dog.jpg','L')
plt.imshow(imbw,'gray')
plt.xticks([])
plt.yticks([])
plt.show()
```

- Question: Apply $L_1\,$ norm to image, and guess what kind of an image will be produced ?

In [17]:

```
row, col = imbw.shape
n = row * col

imbws = imbw.reshape(-1, 1)

beta = 50000

x = cvx.Variable(n)
obj = cvx.Minimize(cvx.norm(x-imbws,2))
const = [cvx.norm(x[1:n] - x[0:n-1],1) <= beta]
prob = cvx.Problem(obj, const).solve('SCS')

imbwr = x.value.reshape(row, col)

plt.imshow(imbwr, 'gray')
plt.xticks([])
plt.yticks([])
plt.show()</pre>
```

Cartoonish effect

In [18]:
